**Balloon Occlusion Device
Having A Proximal Valve**

Claim of Priority

5 The present application claims priority under 35
U.S.C. § 119 to United States Provisional Application
Serial No. 60/212,187 filed on June 16, 2000, entitled
"Angioplasty Catheter", the entirety of which is
incorporated by reference herewith.

1. Field of the Invention

10 The present invention relates to medical devices,
specifically a medical device having a low profile valve
for selectively inflating and deflating an inflatable
balloon disposed upon the medical device, wherein the
valve allows passage of interventional devices over the
15 medical device during use.

2. Background of the Invention

In order to perform many vascular procedures a
guidewire is initially inserted into the patient's
vasculature. The guidewire is generally inserted into

the patient through an incision created in the patient's femoral artery. After the guidewire has been placed within the patient's vasculature, other interventional devices such as catheters may be passed over the
5 guidewire. As used herein, the term "interventional device" is intended to include, but not be limited to, any known device capable of being inserted within the human vasculature for diagnosis, treatment or inspection thereof. Additionally the terms "catheter" and
10 "guidewire" as utilized herein are intended to be interchangeable when referring to the medical device in accordance with the present invention.

One difficulty associated with this procedure however is that the guidewire must be held in place
15 while the interventional device is passed over the guidewire. It is possible that the guidewire may become dislodged from the position where it was initially placed, therefore when a interventional device is advanced over the guidewire it may not be advanced to
20 the desired position.

A common medical procedure where it is desirable to place a guidewire and then advance interventional devices over the guidewire are angioplasty and/or bypass

procedures. In an angioplasty procedure, the guidewire
may be advanced up to or through a blockage in a
patient's vessel, wherein a catheter containing a stent
or other interventional device is then passed over the
5 guidewire to the occluded area.

A common procedure performed on occluded or
narrowed vessels is to place an angioplasty catheter
having a balloon disposed on one end within the occluded
region and expanding the balloon, thereby expanding the
10 vessel. The balloon catheter is typically formed of a
flexible material wherein the catheter includes
radiopaque markings thereon in order to properly place
the balloon within the desired region. The balloon
catheter is placed within the patient's vasculature
15 through a percutaneous access site such as the femoral
artery. The balloon catheter is placed within the
patient's vasculature by tracking the catheter over a
guidewire which has been placed first. The guidewire
enables a user to more easily track the flexible
20 catheter into a proper position, wherein the balloon may
be inflated to expand the vessel and/or occlusion
therein.

Another commonly utilized cardiovascular procedure is stenting. Stenting is a procedure wherein a expanding device is placed within an obstructed vessel in order to hold open or expand the constricted vessel.

5 Stenting procedures are carried out in a manner similar to the balloon angioplasty procedure described above. Many times both procedures will be performed wherein the vessel may be first expanded with a balloon catheter and subsequently a stent will be deployed thereafter to
10 maintain the expanded diameter of the vessel.

During stenting and/or balloon angioplasty procedures there is the risk that plaque or other debris may be dislodged from the inner walls of the vessel. The plaque may be in the form of small particles which
15 may be carried within the patient's blood stream and may lead to other complications such as embolism if the particles become lodged into a branch vessel or artery and restrict or prevent blood flow to that vessel or artery.

20 Therefore it is desirable to provide a device which may be utilized during a medical procedure such as those described above wherein the device may be utilized to prevent dislodged particles from flowing into a

patient's blood stream and potentially causing further
blockage or a stroke. It is also desirable to provide
a device which may be utilized to temporarily occlude a
vessel distal an area where a surgical procedure is to
5 be performed thereby providing a contained area for the
surgeon to operate within.

One such device has been disclosed in U.S. Patent
No. 5,807,330 to Teitelbaum, the entirety of which is
incorporated by reference herewith. However, there
10 remains a desire for an improved low profile valve for
the device of Teitelbaum.

A further object of the present invention therefore
is to provide a medical device having a low profile
valve means disposed on the proximal end portion,
15 wherein the valve may be selectively opened and closed
thereby enabling the inflation and deflation of a
balloon disposed at the distal end portion of the
device. Furthermore, the valve provides a sufficiently
low profile area wherein other interventional devices
20 may be passed over the medical device to conduct
surgical procedures within the patient's vasculature.

A further object of the present invention is to
provide an medical device wherein an balloon disposed

upon the distal end portion of the device may be selectively inflated or deflated through a valve means wherein the inflation device is removable from the valve means.

5

SUMMARY OF THE INVENTION

In one aspect of the invention there is provided a medical device for vessel occlusion, the medical device including an elongated body having a distal end portion, a proximal end portion, and a lumen disposed therethrough. The medical device further includes an inflatable balloon disposed at the distal end portion of the elongated body, the balloon being in fluid communication with the lumen, and an opening defined at the proximal end portion of the elongated body, the opening being in fluid communication with the balloon via the lumen. A valve body is moveably disposed at the proximal end portion of the elongated body; the valve body being movable between a closed position and an open position. The valve body is configured to engage a surface of the elongated body, distal to the opening, to seal the opening when the valve body is in the closed position.

033297-005

In another aspect of the invention, there is provided a medical device for vessel occlusion. The medical device includes an elongated body having a distal end portion, a proximal end portion, and a lumen disposed therethrough. The medical device further includes an inflatable balloon disposed at the distal end portion of the elongated body, the balloon being in fluid communication with the lumen. An opening is defined at the proximal end portion of the elongated body, the opening being in fluid communication with the balloon via the lumen. A valve body is moveably disposed at the proximal end portion of the elongated body, the valve body being movable between a closed position and an open position. The valve body is configured to engage an outer surface of the elongated body to seal the opening when the valve body is in the closed position.

In another aspect of the present invention there is provided a medical device for vessel occlusion, the medical device including an elongated body having a distal end portion, a proximal end portion, and a lumen disposed therethrough. The medical device further includes an inflatable balloon disposed at the distal

end portion of the elongated body, the inflatable
balloon being in fluid communication with the lumen. An
opening is defined at the proximal end portion of the
elongated body, the opening being in fluid communication
5 with the balloon via the lumen. A valve body is
moveably disposed at the proximal end portion of the
elongated body, the valve body being movable between a
closed position and an open position. The valve body is
configured to engage an outer surface at the proximal
10 end portion of the elongated body, distal to the
opening, to seal the opening when the valve body is in
the closed position. The valve body includes a side
wall having a cavity defined therein to receive the
proximal end portion of the elongated body, and an outer
15 surface substantially flush with an outer surface of the
distal end portion of the elongated body when in the
closed position. At least one of the valve body and the
elongated body has a projection extending therefrom for
mating engagement with the other body to prevent
20 inadvertent movement of the valve body at least when in
the closed position.

DETAILED DESCRIPTION OF THE DRAWINGS

The objects and advantages of the invention will become apparent from the following detailed description of preferred embodiments thereof in connection with the accompanying drawings in which like numerals designate
5 like elements and in which:

DETAILED DESCRIPTION OF A PREFERRED EMBODIMENT

In accordance with the present invention there is shown and described a medical device for vessel occlusion. The medical device includes an elongated
20 body having a distal end portion, a proximal end portion, and a lumen disposed therethrough. A balloon is disposed at the distal end portion of the elongated

body, the balloon being in fluid communication with the lumen. An opening is defined at the proximal end portion of the elongated body, the opening being in fluid communication with the balloon via the lumen. A
5 valve is disposed at the proximal end portion of the elongated body, the valve including a valve body movable between a closed position and an open position. The valve body is configured to engage a surface of the elongated body, distal to the opening, to seal the
10 opening when the valve body is in the closed position.

Referring now to Figures 1, 2, and 11, there is shown a representative embodiment of a medical device 100 according to the present invention. The medical device 100 includes an elongated body 105 having a
15 proximal end portion 104 and a distal end portion 102 and at least one lumen 101 disposed therethrough defining an inner cavity. An inflatable balloon 120 is disposed proximate the distal end portion 102, wherein the inner cavity of the balloon 120 is in fluid
20 communication with the lumen 101 of the medical device 100.

If desired, at least one radiopaque marker 108 may be disposed at the distal end portion of the elongated

body 105 proximate the balloon 120. Preferably, at least one radiopaque marker 108 is disposed within the distal end of the cavity defined by the balloon, and if desired, at least one proximal radiopaque marker 106 is
5 disposed within the proximal end of the cavity defined by the balloon. The medical device 100 also may include a flexible tip 160. The flexible tip 160 may extend from the distal end portion 102 of the medical device 100.

10 In accordance with the present invention, the medical device 100 includes at its proximal end portion 104 a valve body 150, wherein the valve body 150 is movable between a closed position and an open position; the valve body configured to engage a surface of the
15 elongated body to seal the opening when the valve body is in the closed position. The medical device 100 will be described in greater detail below.

The elongated body 105 of the medical device 100 may be constructed of any suitable material including
20 but not limited to polyimide material, alloy materials, and metallic materials such as stainless steel hypodermic tubing which is available from MicroGroup® Inc., Medway, MD. Preferably the elongated body 105 of

the medical device 100 is constructed of a nickel
titanium alloy known as Nitinol. Materials such as
these are available from various suppliers such as Memry
Corp., Menlo Park, CA US. The above materials should
5 not be considered limiting in any manner, it is
contemplated that the elongated body 105 may be
constructed of any bio-compatible material. For
example, the elongated body may be constructed of a
polymer such as polyimide tubing from HV Technologies,
10 Inc. of Trenton, GA US. The elongated body 105 may be
manufactured using well known techniques such as
swaging, machining, grinding, electropolishing, EDM,
heat forming, extruding, or by any other processes
commonly used to shape and configure small metal or
15 polymer components. Additionally, the elongated body
105 may be constructed from polypropylene or urethane by
an extrusion process using an extruder such as that
available from Medical Extrusion Technologies, Inc.
Murieta, CA US.

20 The elongated body 105 may be further coated with
any of a variety of materials to enhance performance if
desired. For example possible coating materials include
lubricious materials such as Teflon® available from

DuPont De Nemours, Wilmington, DE US, and hydrophobic materials such as silicone lubricant dispersion PN 4097, available from Applied Silicone Corp., Ventura, CA US, or a hydrophilic materials such as hydrogel available
5 from Hydromer, Branchburg, NJ US, or lubricious coatings such as those available from Hydro-Silk of Merritt Island, Florida, under the trade name TUA Systems.

The elongated body 105 may have any suitable cross-sectional shape, including elliptical, polygon, or
10 prismatic, although a circular cross-section generally is preferred. The cross-sectional dimension generally is between about 0.01 millimeters to about 1.0 millimeters, preferably between about 0.10 millimeters and about 0.50 millimeters, most preferably between
15 about 0.250 millimeters and about 0.450 millimeters. Furthermore the medical device 100 may have an overall length between about 180 centimeters and 400 centimeters, preferably between about 250 centimeters and about 350 centimeters, more preferably the medical
20 device has a length between about 290 centimeters and about 310 centimeters, and most preferably about 300 centimeters.

Referring now to Figure 2 there is shown a partial cross-sectional side view of the distal end portion 102 of the medical device 100. As shown in Figure 2, a flexible tip 160 may extend from the distal end portion 102 of the elongated body 105. A variety of distal tip configurations are known and used in the art, each generally capable of performing particular functions. For example, and as embodied herein, the flexible tip 160 is constructed of a solid inner core wire 162 of type 304 stainless steel, wherein the solid core 162 is wrapped with a bio-compatible wire 164. Examples of a bio-compatible wire 164 which may be utilized include stainless steel, Nitinol, Titanium, Platinum, Iridium, and similar bio-compatible materials. In a preferred embodiment the bio-compatible wire 164 is platinum wire. Platinum wire is preferably used because platinum wire is visible under fluoroscopy thereby enabling a surgeon to locate the flexible tip 160 within a patient's body in use. By utilizing a solid inner core 162 for the flexible tip 160, the distal tip may include a pre-formed curve 169 as shown in Figure 2. The pre-formed curve 169 in addition to a blunt tip 167 form an atraumatic tip thereby allowing the medical device 100 to

be inserted within a patient's vasculature. The pre-formed curve 169 ensures that the blunt tip 167 does not pierce the vessel/artery or organ through which the medical device 100 is being advanced. It shall be understood that the pre-formed curve 169 remains sufficiently pliable and elastic whereby an interventional device may be advanced over the outer diameter of the medical device 100 such that the pre-formed curve 169 will straighten and allow the medical device to pass over. Such tip designs are well known in the art.

As shown in Figure 2, the proximal end 166 of the flexible tip 160 as embodied herein is adapted to be received within the lumen 101 of the medical device 100.

The proximal end 166 of the flexible tip 160 may be secured within the lumen 101 through the use of a bio-compatible adhesive, such as Loctite® 4014, or through mechanical fastening methods such as soldering or a friction fit. In a preferred embodiment, the distal end portion 102 of the elongated body 105 is deformed about the diameter of the distal end 166 of the flexible tip 160, thereby forming a fluid tight seal between the lumen 101 and the flexible tip 160.

In accordance with another embodiment of the invention, referring now to Figure 2B there is shown an alternative embodiment of the flexible tip 160 as described above. As shown in Figure 2B, the flexible tip 160 may be constructed in the same or similar manner as that described above, wherein like reference numerals have been utilized to denote similar features. The flexible tip 160 of Figure 2B further includes a proximal end 166, wherein the proximal end 166 is adapted to be detachably received within the lumen 101 of the elongated body 105. In use, it is desirable to pre-prime the medical device 100, that is to remove as much air as possible from the lumen 101 as well as the chamber 123 defined by the balloon 120. Typically this is done by drawing a vacuum within the lumen 101 and chamber 123 and allowing a bio-compatible fluid such as saline or contrast to fill the lumen 101 and chamber 123 of the medical device 100. Although most air is removed from the system, removal of 100% of the air typically may not be possible. By constructing the medical device 100 with a removable tip as shown in Figures 2B and 4, a bio-compatible fluid may be flushed distally through the lumen 101 and the chamber 123 thereby forcing air out of

these spaces. After the air has been forced through the medical device 100, the flexible tip 160 is attached to the distal end portion 102 of the elongated body 105, wherein the medical device 100 is ready for use.

5 As previously noted, an inflatable balloon is provided at the distal end portion of the medical device of the present invention. The balloon 120 may be constructed of any suitable, flexible bio-compatible materials depending upon the intended function of the
10 medical device 100. The balloon may be inelastic, if desired, although generally elastic materials are preferred. Examples of materials of which the balloon 120 may be formed are urethane, polyvinyl chloride, silicone or other similar materials which have good
15 elastomeric properties. Preferably the balloon 120 is constructed of C-Flex, which is available from Consolidated Polymer Technologies, Inc. of Largo, Florida, USA. The C-Flex material allows for the formation of a balloon having very specific durometers,
20 thereby enabling the balloon to be specifically tuned to be responsive to a pre-determined force. For example, if a pressure of one atmosphere or about 14 psi is available to be applied to a balloon and it is desirable

to inflate the balloon from a first diameter of 0.90 millimeters to a second diameter of about 6 millimeters, the durometer of the C-Flex may be adjusted thereby allowing for a balloon to be formed which will expand from the first diameter to the second desired diameter in response to the applied force.

As embodied herein, specifically with reference to Figures 1 and 2, the balloon 120 may be radially disposed at the distal end portion 102 of the elongated body 105, wherein the balloon 120 is in fluid communication with the lumen 101 of the elongated body 105 through at least one aperture 107 formed within the wall of the elongated body 105. The aperture 107 may be formed having a generally cylindrical geometry or the aperture may be formed as an elongated slit within the wall of the elongated body 105. Furthermore, it is contemplated that the aperture 107 may be embodied having many different geometric shapes and the examples above and those which are shown in the Figures are merely exemplary.

Alternatively, the balloon 120 may be disposed asymmetrically upon only a portion of the outer wall circumference if desired. Furthermore, if desired, the

proximal end of the balloon 120 may be disposed about
the extreme distal end of the elongated body 105 as
shown in Figure 3, and as further depicted by U.S.
Patent No. 5,807,330, to George P. Teitelbaum, entitled
5 "Angioplasty Catheter," the entirety of which is hereby
incorporated by reference.

As shown in Figure 3, the distal end 121 of the
balloon 120 may be attached to a support member 180,
wherein the support member 180 may be disposed within
10 the lumen 101 of the elongated body 105. The support
member 180 may extend beyond the distal end 121 of the
balloon 120, such that the distal end 182 of the support
member 180 functions in the manner as described above
with reference to the flexible tip 160. Inflation of
15 the balloon 120 as shown in Figure 3 is accomplished
through the distal end portion 102 and lumen 101 of the
elongated body 105.

As embodied in Figures 4 and 5, the balloon 120 may
be disposed about a balloon support member 140, wherein
20 the balloon support member 140 is adapted to be received
within the lumen 101 of the elongated body 105 as shown,
or about the outer surface of the elongated body 105.
The balloon 120 as shown in Figures 4 and 5 is similar

098823 054504

to that shown and described above with reference to
Figures 1-3, wherein like numerals designate similar
features. As shown in Figures 4 and 5, the chamber 123
of the balloon is in fluid communication with the lumen
5 101 through an aperture 107' formed in the balloon
support member 140, wherein the balloon support member
may be constructed of the same material as that of the
elongated body 105. Alternatively, the balloon support
member may be constructed of any one of the materials
10 described above with reference to the elongated body 105
and the balloon 120.

The balloon 120 may be integrally formed onto the
elongated body 105 adjacent to the distal end portion
102 of the elongated body 105 through dip forming, spray
15 forming, extrusion, heat forming, or similar
manufacturing processes. Preferably the balloon 120 is
formed independent of the elongated body 105 by
employing one of or a plurality of the processes above
and then fixedly attached to the elongated body 105.
20 Prior to affixing the balloon 120 to the elongated body
105, any coating applied to the elongated body 105 in
the area where the balloon 120 is to be affixed is first
removed if necessary. The balloon 120 is then

positioned adjacent the distal end portion 102 such that the proximal end 124 and the distal end 122 of the balloon 120 extend beyond the apertures 107 formed in the elongated body 105. The balloon 120 may be fixedly
5 attached to the elongated body with a bio-compatible adhesive such as Loctite® 4014. Heat shrink tubing 125 may be disposed about the proximal end 124 and the distal end 122 of the balloon to further affix the balloon 121 to the elongated body 105.

10 As shown in Figures 2-5, a distal marker band 108 and a proximal marker band 106 may be disposed about the distal and proximal ends of the balloon 120, wherein the marker bands 106/108 may be constructed of a bio-compatible material such as stainless steel, titanium,
15 silver, platinum, gold, radiopaque plastics, or similar materials which may be readily viewed under fluoroscopy. Preferably the marker bands 106/108 are formed of gold. The marker bands 106/108 may be separate pieces which are fixedly attached to the diameter of the elongated
20 body utilizing mechanical methods or adhesives. Preferably, the marker bands are integrally formed upon the diameter of the elongated body through the use of spray coating, electroplating or similar methods which

will deposit the marker band material upon the elongated body. It shall be understood that additional marker bands may be disposed upon the elongated body 105 at any distance along the distal portion 102.

5 A bio-compatible adhesive 112 may be applied to the edges of the heat shrink tubing 125 as shown in Figures 2-5 in order to provide a smooth transition surface between the heat shrink tubing 125 and the outer diameter of the elongated body 105. An example of a
10 bio-compatible adhesive which may be utilize is Loctite® 3311, an ultra-violet cured adhesive.

It shall be understood that the balloon 120 may be disposed about the elongated body 105 at any distance along the distal end portion 102 of the elongated body
15 105, so long as the balloon is sealingly disposed in fluid communication with the lumen 101 of the elongated body 105.

As previously noted, and in accordance with the present invention the medical device also has a valve
20 including a valve body configured to be moveably disposed at the proximal end portion of the elongated body. The valve body is movable between a closed position and an open position, wherein the valve body is

configured to engage a surface of the elongated body, to seal the opening when the valve body is in the closed position.

5 The valve body may be configured to be movable in either an axial or radial direction. In a preferred embodiment, the valve body can be moved axially between a sealed position and an opened position, and moved radially to engage or disengage a locking mechanism disposed upon the proximal end portion of the medical
10 device.

The valve body when in a closed position is preferably flush with the outer diameter of the elongated body 105. By providing such a low profile valve body, interventional devices may be easily passed
15 over the medical device. In an alternative embodiment, it is contemplated that the valve body may have a diameter greater than that of the elongated body 105, so long as the outer diameter of the valve body is not so large as to inhibit the passage of interventional
20 devices thereover.

Referring now to Figure 9, there is shown a preferred embodiment of the valve body 150 in accordance with one aspect of the present invention. The valve

body 150 includes a proximal end portion 154 and a
distal end portion 152, and a cavity 156 formed
therebetween. The distal end portion 152 of the valve
body is adapted to sealingly engage the outer diameter
5 of the elongated body as shown in Figure 11.

The cavity 156 of the valve body 150 may further
include a pliable coating to aid in the sealing of the
valve body to the elongated body 105. The coating may
be silicone, urethane, TFE. In a preferred embodiment
10 the pliable coating is a parylene coating. The valve
body 150 may be constructed of a bio-compatible material
such as titanium, stainless steel, polyurethane,
polyvinyl chloride, Nitinol, or similar materials,
wherein the valve body further has a closed proximal end
15 portion 154, such as a plug 158 disposed within the
lumen 151 of the valve body 150. The plug 158 may be
formed of the materials listed above. In a preferred
embodiment the plug 158 may be formed of solder, wherein
a solder, such as that described above may be utilized
20 to form the plug 158.

Referring now to Figure 10 there is shown another
embodiment of the valve body 150 in accordance with the
present invention. The valve body 150 shown in Figure

10 may further include a beveled section 156, wherein
the beveled section 156 may be formed at an angle β
between about 0 and about 90 degrees, preferably between
about 30 and about 60 degrees, more preferably the bevel
5 156 is formed having an angle of about 45 degrees. The
bevel 156 is adapted to receive the step 117, as shown
in Figure 11, wherein the step may be formed adjacent
the proximal end portion 104 of the elongated body 105,
wherein the bevel 156 and step 117 form a fluid tight
10 seal between the valve body 150 and the elongated body
105.

In accordance with the present invention, referring
now to Figures 6, 9, and 11 there are shown partial
cross-sectional side views of a first representative
15 embodiment of the medical device 100. The proximal end
portion 104 of the medical device 100 is shown in
Figures 6, 9, and 11. Figures 9 and 11 illustrate a
first representative embodiment of the valve body 150,
wherein as shown in Figure 11, the valve body 150 can be
20 disposed about the proximal end portion 104 of the
elongated body 105. The valve body 150 includes an
elongated body having a proximal end portion 154 and a
distal end portion 152, wherein the distal end portion

152 is adapted to sealingly receive the elongated body
105 of the medical device 100, and the proximal end
portion has a closed or blind end 158. As embodied
herein, the valve body 150 therefore is moved axially
5 between an open position and a closed position as
described in greater detail below.

The valve body may be constructed of any suitable
bio-compatible material such as titanium, Nitinol,
polyimide, and other bio-compatible plastics. In a
10 preferred embodiment the valve body is constructed of a
stainless steel tube, wherein the proximal end 154 of
the tube is sealed with a plug 158. The plug 158 may be
constructed of a bio-compatible material such as
titanium, Nitinol, stainless steel, nylon, delrin, and
15 other similar materials. In a preferred embodiment the
plug 158 is constructed of solder available from Kester
of Des Plains, IL, wherein the solder is preferably
lead-free. It is further contemplated that the valve
body may be constructed of a unitary body wherein the
20 valve body may be injection molded and being constructed
of plastics or metals.

The valve body 150 defines a cavity 151 therein to
receive the outer diameter of the elongated body 105.

10

15

about 60 degrees and more preferably the angle is about 45 degrees. In this manner, the outer surface of the valve body is substantially flush with the outer surface of the elongated body 105 distal to the step 117. It is
5 further contemplated that the step 117 may be formed having a convex or concave radius (not shown). That is instead of being formed as a linear transition between the two diameters, the step 117 may form a gradual radius between the two diameters, the gradual radius
10 embodied as either convex, concave or a combination thereof.

If desired, the proximal end portion 104 of the elongated body 105 may have a closed or blind end, such as by providing a plug 103 disposed to seal the lumen
15 101 as shown in Figure 6. The plug may be constructed of a bio-compatible material such as titanium, stainless steel, Nitinol, delrin, nylon, or similar materials. The plug 103 embodied herein is affixed within the lumen 101 of the elongated body with a bio-compatible adhesive
20 which will adhere to the plug 103 and the inner wall of the lumen 101. In a preferred embodiment, the plug 103 is formed of solder such as that described above with regard to the valve body 150. Alternatively, the plug

103 is not necessary because the distal end 152 of the valve body 150 sealingly contacts the outer diameter of the elongated body 105 thereby creating hemostasis within the medical device 100. It shall be understood
5 that if the plug 103 is not disposed within the lumen 101 of the elongated body 105, the valve body 150 must include the plug 158 in order to form a fluid tight seal within the elongated body 105.

Referring now to Figures 11 and 12 there is shown
10 the medical device 100 in accordance with one aspect of the present invention in use. As shown in Figure 11, the valve body 150 is disposed upon the proximal end portion 104 of the elongated body 105, wherein the valve body is in a closed position. The distal end 152 of the
15 valve body forms a fluid tight seal with the step 117 of the elongated body 105. The fluid tight seal may be formed through an interference fit between the distal tip 152 of the valve body and the step 117 or
alternatively, as described herein the inner diameter
20 of the valve body may include a parylene coating for enhanced sealing properties. Referring now to Figure 12 there is shown the valve body 150 in an open configuration. Wherein, when the valve body 150 is in

an open configuration, inflation fluid may be introduced into the lumen 101 of the elongated body 105 thereby inflating the balloon 120 of the distal tip portion 102.

Inflation fluid may be introduced in a manner such as that disclosed by Teitlebaum, U.S. Patent No. 5,807,330. Alternatively, inflation fluid may be withdrawn from the lumen 101, thereby deflating the balloon 120. As shown in Figures 11 and 12, the valve body 150 may be selectively opened and closed in order to control the inflation and deflation of the balloon 120. To move the valve body between an opened and closed position as shown an axial force or a radial force or a combination thereof may be applied to either or both the valve body 150 or the elongated body 105. Additionally, the valve body 150 only need be moved between about .005 inches and about 1.0 inches, preferably between about .02 inches and about .75 inches, most preferably between about .05 inches and about .25 inches.

Another alternative embodiment in accordance with the present invention is illustrated in Figure 33, wherein there is shown a medical device 100 having a valve body 150 disposed upon the proximal end portion 104 of the elongated body, wherein the plug 158' of the

valve body forms a fluid tight seal with the very proximal end 137 of the elongated body 105. The plug 158' may further include a pliable coating as those described above in order to effectuate a better seal with the proximal end 137 of the elongated body 105.

Furthermore, frictional interference between the chamber 156 of the valve body and the outer diameter of the elongated body 150 act to retain the valve body 150 upon the proximal end portion 104 of the elongated body 105.

It shall be understood that the medical device 100 embodied and described with reference to Figure 33 may be adapted to include any other feature described herein in relation to other embodiments of the medical device 100.

Referring now to Figures 7, 13-14, 18, and 19 there is shown an alternative representative embodiment of the reduced diameter area according to the present invention. As shown in Figures 7, 13-14, 18, and 19, the reduced diameter area may include a plurality of steps, wherein the first step 117 transitions the outer diameter of the elongated body 105 to a first reduced diameter section 115 as described above. A second step 118 may be disposed proximal to the first step 117,

wherein the second step 118 provides a transition
between the first reduced diameter portion 115 and a
second reduced diameter portion 116.

5 The second step 118 may be formed at an angle
between about 0 and about 90 degrees, preferably between
about 30 and about 60 degrees, more preferably between
about 40 and about 50 degrees.

As shown in Figures 13 and 14, the second step 118
can provide improved inflation and deflation of the
10 balloon when the valve sleeve 150 is moved proximally
into an opened position. This is because, as the valve
body is moved from a closed position to an opened
position, the valve body 150 does not have to be moved
past the openings 113 formed in the wall of the
15 elongated body 105. That is, once the distal end 152 of
the valve body 150 passes proximal the second step 118
as shown in Figure 14, a fluid flow path is formed
between the second reduced diameter portion and the
cavity 151 of the valve body 150. Indeed, by providing
20 such a flow path, the extreme proximal end of the
elongated body as shown in Figures 13 and 14, can be
used to define an opening for inflation of the balloon

such that additional openings need not be provided in the wall of the elongated body 105.

Referring now to Figures 8 and 15 there is shown yet another alternative embodiment of the proximal end portion 104 of the medical device 100 in accordance with the present invention. As shown in Figures 8 and 15, the proximal end portion 104 of the medical device 100 may include tapered section 515, which can be formed by known techniques, such as grinding, milling, EDM, laser cutting, or swagging. The embodiment herein defines a constant angle of between about 0 and about 45 degrees, preferably between about 0 and about 10 degrees, more preferably between about .5 and about 3 degrees. As shown in Figure 15 a valve body 150 is disposed about the tapered section 515, wherein the distal end 152 of the valve body contacts the outer surface of the elongated body 105 thereby sealing the openings 113 when in a closed position. The valve body 150 may be moved axially, whereby an annular space is created about the distal end 152 of the valve body 150 and the tapering outer diameter of the elongated body 105, thereby allowing for fluid to flow from the annular space into the lumen 101 and the chamber 123 of the balloon.

In accordance with the present invention an opening is provided at the proximal end portion 104 of the elongated body 105, the opening being in fluid communication with the balloon 120 via the lumen 101 of the elongated body 105, wherein the opening may be embodied in a variety of configurations. As previously noted, the opening may be defined as the extreme proximal end of the elongated body. Alternatively, and as embodied herein, the opening may include at least one opening 113 disposed through the wall of the elongated body 105 at the proximal end portion 104 thereof. Preferably, and when the proximal end portion 104 is provided with an area of reduced cross-section, the opening is located within the reduced diameter area 115 of the proximal end portion 104 of the elongated body 105.

In accordance with the present invention, the opening 113 may be formed in a variety of manners, some of which are illustrated in Figures 6-8, and 11-32. As shown in Figures 6-8 and 11-32, a plurality of openings may be formed through the wall of the reduced diameter sections 115 and 116, wherein the openings are disposed along the proximal end portion 104 of the elongated body

105. The openings 113 may be formed within the wall of
the elongated body utilizing manufacturing processes
such as laser drilling, EDM, drilling, milling,
electrochemical milling, and other similar procedures
5 that will produce an opening through the wall of the
elongated body 105.

Referring now to Figures 16 and 18, there is shown
a first alternative embodiment of the opening 213 in
accordance with the present invention, wherein like
10 numerals denote similar features as described above with
reference to the medical device 100 of the present
invention. The opening 213 may be embodied in the form
of at least one axially extending slit formed within the
wall of the reduced diameter portion 115 or second
15 reduced diameter portion 116.

Referring now to Figures 17, 19, and 29 there is
shown a second alternative embodiment of the opening 313
in accordance with the present invention. The opening
313 may be embodied as a skive within the wall of the
20 reduce diameter portion 115 or second reduced diameter
portion 116. The skive may be formed within the wall of
the elongated body 105 by passing a grinding wheel over

the portion of the elongated body where the skive 313 is to be formed.

In accordance with the invention, there are provided additional alternative embodiments in accordance with the medical device of the present invention. As previously discussed, the medical device includes a proximal end portion and a valve body disposed thereon, wherein the valve body is movable between an open position and a closed position, in a closed position the valve body sealingly engages the outer wall of the elongated body. In an open position the valve body allows for the inflation or deflation of the balloon as previously discussed.

Referring now to Figure 24, the elongated body 105 and the valve body 450 includes each of the elements described above and illustrated in Figure 11. Additionally, the elongated body 105 includes a slot 413 formed within the wall of the elongated body 105 wherein the slot 413 is axially aligned with the elongated body 105. The slot 413 may be formed partially into the outer wall, such as by a groove or dimple, or extend entirely through the wall of the elongated body 105 as an opening. The valve body 450 is disposed about the

proximal end portion 104 of the elongated body 105 in the manner as described above. The valve body 450 may further include a protrusion 455 extending into the cavity 456 of the valve body. The protrusion 455 is
5 slidably received within the slot 413 of the elongated body 105. The protrusion 455 therefore may retain the valve body 450 upon the proximal end 104 of the elongated body 105, and limit the proximal movement of the valve body. The protrusion 455 also may further
10 provide tactile feedback to a user indicating whether the valve body is in an opened or closed configuration. The protrusion may be formed as a separate body attached to the valve body 450, or the protrusion may be formed integral with the valve body 450. Alternatively, the
15 reduced diameter section may include a protrusion, either integrally formed therewith or fixedly attached thereto and the valve body may include a slot or groove adapted to receive the protrusion of the reduced diameter section.

20 Referring now to Figures 20-22, there is shown an alternative embodiment of the valve body 550 and reduced diameter portion 515. The reduced diameter portion 515 further includes a groove 519, formed in the wall of the

elongated body 105. The groove 519 may be formed in the wall of the elongated body by machining, grinding, EDM milling, or similar manufacturing processes.

Alternatively, the groove 519 may be formed by deforming
5 the wall of the elongated body as shown in Figure 30.

The valve body 550 includes a pin 555 or similar protrusion extending into the cavity 556. When the valve body 550 is disposed about the reduce diameter portion 515, the pin 555 is received within the groove
10 519, wherein the groove 519 guides the pin 555 during translation of the valve body 550 between an opened position and a closed position. The groove 519 may be axially aligned with the lumen 101 of the elongated body 105 as shown in Figures 20-22, or extend helically to

15 induce rotational movement of the valve body during displacement. Alternatively, the groove 519' may be both axially and radially aligned with the lumen 101 of the elongated body 105 as shown in Figure 23. By having a groove 519' that is both axially and radially aligned
20 requires that the valve body 550 be rotationally translated first and then axially translated in order to open the seal between the valve body and the elongated body. This greatly reduces or eliminates the

possibility of the valve body 550 from being
accidentally opened.

Referring now to Figures 25-27 there is shown
another alternative embodiment in accordance with the
5 medical device of the present invention. Referring now
to Figure 25 there is shown a partial cross-sectional
side view of an alternative embodiment of the proximal
end portion 904 of an elongated body 905, wherein the
proximal end portion 904 further includes a pin 990
10 disposed axially through the walls and lumen 901 of the
proximal end portion 904. Better understanding of the
location of the pin 990 may be understood with reference
to the cross-sectional top view of Figure 26
illustrating the pin 990 being disposed through the
15 proximal end portion 904 of the elongated body 905
perpendicular to the top view. Referring now to Figure
27, there is shown a corresponding embodiment of a valve
body 950, wherein the valve body 950 includes a track
930. The track provides a guide for positioning the
20 valve body 950 when the groove 930 engages the pin 990.
A step 917 forms a tapered portion on the proximal end
of the valve body 950, wherein then the valve body 990
is inserted within the lumen 901 of the elongated body

905 the tapered portion engages the inner diameter of
the proximal end portion of the elongated body therefore
forming a fluid tight seal. In order to effectuate a
seal between the tapered portion of the valve body 950
5 and the lumen 901 of the proximal end portion 904 of the
elongated body 905 involves two movements, one axial
movement and a second rotational force. The second
rotational force requires that a deliberate action on
the part of an operator to disengage the seal once the
10 seal has been formed. The second action of the
rotational force also makes it more difficult for the
operator to inadvertently open the port by merely
pulling axially on the valve body 950. Alternatively,
the pin 990 can extend beyond the outer surface of the
15 elongated body, and the valve body can be configured to
be disposed about the outside of the proximal end
portion of the elongated body with the groove being
formed on an inside surface of the valve body.

The track 930 may be formed within the outer
20 surface of the valve body 950 utilizing any of the
processes as described above.

Referring now to Figures 28-32, there is shown an
additional alternative embodiment in accordance with the

present invention. Referring to Figure 28 there is shown partial cross-sectional top view of a medical device 800, wherein the medical device 800 includes an elongated body 805 having a distal portion (not shown) and a proximal end portion 804, wherein the proximal end portion 804 includes at least one groove formed therein as shown in Figure 30. The medical device 800 further includes an opening 815 disposed adjacent to the proximal end portion 804 of the elongated body 805. As shown in Figure 29, the opening 815 may be formed as a skive. Although the opening 815 is shown to be embodied as a skive this should not be considered limiting in any manner, it is contemplated that any of the openings described herein may be utilized in addition to or as an alternative to the skive. The skive 815 may be formed utilizing any of the methods described above.

Referring now to Figure 31 there is shown a valve body 850, wherein the valve body includes a proximal end portion 854 and a distal end portion 852 and a tapered portion 817 disposed therebetween.

As shown in Figures 28 and 32, the valve body 850 is disposed proximally within the lumen 801 of the medical device 800 when in the opened position, To

close the medical device, the valve body 850 is advanced distally within the lumen 801 of the elongated body 805 until the tapered section 817 passes the distal portion of the opening 815 and engages the inner surface of the proximal end portion of the elongated member. If desired, a groove and protrusion configuration also can be provided. In this manner, the valve body 850 is then rotated to lock the valve body 850 into place.

Therefore, as described above with regard to Figures 25-27 the valve body cannot be inadvertently removed from the inner lumen 801 of the elongated body 805 without first applying a rotational force to the valve body 850.

The alternative embodiments of the medical device 900 and 800 illustrated in Figures 25-32 may be constructed according to the aspects and methods described above wherein the same materials may also be utilized. In addition, the valve bodies 950 and 850 may further include a coating such as that described above with regard to Figures 9 and 10 and the valve body 150 disclosed therein to effectuate a better seal upon the medical device 900 and 800.

The groove 830 formed within the proximal end portion 804 of the elongated body 805 may be formed

utilizing any of the methods described above with reference to the medical device 100. Preferably the groove 830 is formed within the side wall of the elongated body through a crimping or dimpling process.

5 The medical device 100 described and illustrated herein may be utilized in vascular interventional procedures such as angioplasty or stenting. In such procedures, an access site to the patient's vasculature is formed, typically within the patient's femoral
10 artery. The patient is systematically heparinized during the procedure. Via the femoral artery approach, a long 9-French access sheath is inserted through the common femoral artery and is advanced into a desired position. Once access has been established, the medical
15 device 100 is inserted into the patient's vasculature.

 Through the use of fluoroscopy and the soft steerable flexible tip 160 of the medical device 100, the medical device 100 is placed adjacent a site in which a medical procedure is to be performed. Placement
20 of the medical device 100 can be confirmed by fluoroscopy confirmation of the plurality of marker bands 108/106 disposed upon the distal end portion 102 of the medical device 100. The balloon 120 may then be

inflated by opening the valve body 150, wherein
inflation fluid may be introduced through the openings
113 in the proximal end portion of the medical device
100, such as described by Teitelbaum, U.S. Patent No.
5 5,807,330. After the balloon 120 is inflated to a
sufficient diameter, the valve body 150 may be moved
into a closed position thereby forming a fluid tight
seal. The balloon 120 remains inflated, while the
source of inflation fluid may then be removed from the
10 proximal end portion 104 of the medical device 100. An
example of a device which may be utilized to introduce
inflation fluid is a Tuohy-Borst device, wherein the
Tuohy-Borst device may be removed from the medical
device 100 as desired. Alternatively, a removable
15 inflator box may be provided, which is capable of
creating a sealed chamber about the proximal end portion
of the elongated member, and allowing selective movement
of the valve body between the open and closed positions
as known in the art. Examples of inflation fluid which
20 may be utilized are saline or carbon dioxide, preferably
contrast fluid is utilized as the inflation fluid
thereby enabling visualization of the balloon 120 under
fluoroscopy.

At this point a balloon angioplasty catheter may be inserted over the medical device 100, wherein the balloon 120 acts to anchor the medical device 100 within the patient's vasculature as well as to occlude the vessel. If desired, the medical device 100 may be utilized to pre-dilate the stenosis within the vessel is the appropriate balloon construction is provided. Alternatively, an angioplasty balloon catheter, and/or a stent delivery device and/or other known interventional devices may be advanced over the medical device 100 to the site to perform a desired procedure as is known in the art. Debris thus created by the interventional device during an interventional procedure can be removed through an aspiration catheter which may be advanced over the medical device 100 as described below.

Following the interventional procedure, the interventional device is removed from the medical device 100 and an aspiration catheter may be advanced over the medical device 100 to a position near the site. Vigorous flushing of the site may be performed by injecting a large volume of saline into the site. Alternatively or additionally, debris may be removed distal the lesion through a lumen of an aspiration

catheter by selectively positioning the aspiration
catheter within the site.

After debris has been removed from the site and the
aspiration catheter is removed from the medical device
100, the valve body 150 is moved from a closed position
to an open position wherein the inflation fluid may be
removed, thereby deflating the balloon 120 of the
medical device 100. At this time the medical device 100
may be withdrawn from the patient's vasculature.

Alternatively, the medical device 100 may remain as
positioned, wherein additional interventional procedures
may be performed at the site, wherein the site may be
aspirated as described following any interventional
procedure. The medical device 100 may remain as
positioned as long as there is a need to perform
additional interventional procedures.

Although the present invention has been described
in considerable detail with reference to certain
preferred embodiments, it is contemplated that one
skilled in the art may make modifications to the device
herein without departing from the scope of the
invention. Therefore, the scope of the amended claims

Patent Application
Atty. Dkt. No. 033297-005

should not be considered limited to the embodiments
described herein.

033297-005
